

Dalsa is a selected derivative of the naturalised strain of Dalkeith. Dalsa is characterised by a very low formononetin and total isoflavone content, high level of hard seededness and very strong seed burial. Dalsa is a «showy» variety with very good herbage and outstanding seed production, seeds are the largest of all subspecies subterranean cultivars. After the establishment year, Dalsa regenerates better than most other strains of early to mid season maturity sub clovers. It has persisted consistently well, equalling Nugarin which it out yields in spring under favourable conditions. Dalsa sub clover is a highly productive, persistent, early season sub clover which is suitable for situations requiring a long term self-regenerating pasture.
